Many biochemists study how pharmaceutical drugs and foods affect an organism's biology. Some also study how environmental toxins are metabolized, and how they may disrupt biological processes. Because biochemistry encompasses all living things, it's a very wide field of study with a range of applications in medicine, agriculture, and the environment.

Environmental chemistry is the scientific study of the chemical and biochemical phenomena that occur in natural places. It should not be confused with green chemistry, which seeks to reduce potential pollution at its source. It can be defined as the study of the sources, reactions, transport, effects, and fates of chemical species in the air, soil, and water environments; and the effect of ...

Students have an option of earning a B.S. in the Environmental Chemistry that is ACS-Certified or not. The ACS certified version is recommended for those who intend to apply to graduate school in Chemistry. The Non-Certified program is designed to prepare students to enter the industrial, government, or legal workforce, or to continue studies in some of the environmental sciences.

Although it is based on toxicology, environmental toxicology draws heavily on principles and techniques from other fields, including biochemistry, cell biology, developmental biology, and genetics. Among its primary interests are the assessment of toxic substances in the environment, the monitoring of environments for the presence of toxic substances, the effects of toxins on biotic and abiotic components of ecosystems, and the metabolism and biological and environmental fate of toxins.

Environmental biochemistry is a part of environmental chemistry, which is the study of the various chemical and biochemical processes occurring in nature. It includes subfields like soil chemistry, atmospheric chemistry and also, aquatic chemistry. This book attempts to understand the multiple branches that fall under the discipline of environmental biochemistry and how such concepts have practical applications. It is compiled in such a manner, that it will provide in-depth knowledge about the theory and practice of the subject. For someone with an interest and eye for detail, this text covers the most significant topics in the field of environmental biochemistry. This textbook is meant for students who are looking for an elaborate reference text on this area.

The first stand-alone textbook for at least ten years on this increasingly hot topic in times of global climate change and sustainability in ecosystems. Ecological biochemistry refers to the interaction of organisms with their abiotic environment and other organisms by chemical means. Biotic and abiotic factors determine the biochemical flexibility of organisms, which otherwise easily adapt to environmental changes by altering their metabolism. Sessile plants, in particular, have evolved intricate biochemical response mechanisms to fit into a changing environment. This book covers the chemistry behind these interactions, bottom up from the atomic to the system's level. An introductory part explains the physico-chemical basis and biochemical roots of living cells, leading to secondary metabolites as crucial bridges between organisms and the respective ecosystem. The focus then shifts to the biochemical interactions of plants, fungi and bacteria within terrestrial and aquatic ecosystems with the aim of linking biochemical insights to ecological research, also in human-influenced habitats. A section is devoted to methodology,

Applying principles of Biochemistry for the protection of environment is the main concern of environmental biochemistry. The main themes include managing water quality and air resources, protection from radiation, to maintain industrial hygiene etc. Environmental biochemists employ living organism and their capabilities for such purposes. The pace of change in environmental biochemistry has continued unabated since 1980. This text discusses the nature of these recent changes and developments, without compromising its principal subject matter. While compiling this book, a serious view has been kept in mind that environmental biochemistry is essentially different from biochemistry. Wherever necessary, diagrams and structures of compounds have been used. Biochemistry is a multidiscipline field that studies the chemistry of life processes. These processes can be loosely divided into the following groups: reactions that are anabolic (build up molecules) or catabolic (break down molecules), chemistry of regulatory pathways (hormones and genes) and the chemistry of cell structure. At the cellular level the reactions include oxidation/reduction reactions, group transfer, hydrolysis, bond making and breaking reactions. On the systemic level the reaction represent pathways and processes in living system that are important in the energy transfer, biological information flow, protein structures,

oxygen flow, and catalysis of reactions. These predefined reactions, processes, pathways and systems all function together enabling the living system to function normally. This book attempts to understand the multiple branches that fall under the discipline of environmental biochemistry and how such concepts have practical applications. Ecological biochemistry concerns the biochemistry of interactions between animals, plants and the environment, and includes such diverse subjects as plant adaptations to soil pollutants and the effects of plant toxins on herbivores. The intriguing dependence of the Monarch butterfly on its host plants is chosen as an example of plant-animal coevolution in action. The ability to isolate trace amounts of a substance from plant tissues has led to a wealth of new research, and the fourth edition of this well-known text has consequently been extensively revised. New sections have been provided on the cost of chemical defence and on the release of predator-attracting volatiles from plants. New information has been included on cyanogenesis, the protective role of tannins in plants and the phenomenon of induced defence in plant leaves following herbivory. Advanced level students and research workers alike will find much of value in this comprehensive text, written by an acknowledged expert on this fascinating subject. Of all the zoological classes the insects are the most numerous in species and the most varied in structure. Estimates of the number of species vary from 1 to 10 million, and 10 individuals are estimated to be alive at any given moment. In their evolution, insects are relatively ancient and, therefore, they have proved to be a phenomenally successful biological design which has survived unchanged in its basic winged form during the last 300 m. y. Insects were the first small animals to colonize the land with full success. Their small size opened many more ecological niches to them and permitted a greater diversification than the vertebrates. What is it about this design that has made insects so successful in habitats stretching from arid deserts to the Arctic and Antarctic and from freshwater brooks to hot springs and salines? Is it due to the adaptability of their behavior, physiology, and biochemistry to changing environmental conditions? Three features of insects are of particular importance in determining their physiological relationship with the environment: their small size, as mentioned above, the impermeability and rigidity of their exoskeleton, and their poikilothermy. Of course, as with any other animals, the insects' success in its environment depends on its ability to maintain its internal state within certain tolerable limits of temperature, osmotic pressure, pH or oxygen concentration (homeostasis).
